I- Directory Data

Each subdirectory (e.g. “08Barcelona”) contains data about a **province**. There is a special directory (“60Spain”) which collects all the information of Spain as a whole.

Contents

Each province subdirectory has:

1. A tab-separated “**txt**” file with all the information at the census-tract level about the province (Note: This data also includes Germany and Great Britain, which we remove afterwards in the paper). The columns are:
 - 1.1. Census tract ID.
 - 1.2. Census tract centroid (Longitude).
 - 1.3. Census tract centroid (Latitude).
 - 1.4. # Residents from Spain.
 - 1.5. # Residents from Germany.
 - 1.6. # Residents from Bulgaria.
 - 1.7. # Residents from France.
 - 1.8. # Residents from Italy.
 - 1.9. # Residents from Poland.
 - 1.10. # Residents from Portugal.
 - 1.11. # Residents from Great Britain.
 - 1.12. # Residents from Romania.
 - 1.13. # Residents from Russia.
 - 1.14. # Residents from Ukraine.
 - 1.15. # Residents from Algeria.
 - 1.16. # Residents from Morocco.
 - 1.17. # Residents from Nigeria.
 - 1.18. # Residents from Senegal.
 - 1.19. # Residents from Argentina.
 - 1.20. # Residents from Bolivia.
 - 1.21. # Residents from Brazil.
 - 1.22. # Residents from Colombia.
 - 1.23. # Residents from Cuba.
 - 1.24. # Residents from Chile.
 - 1.25. # Residents from Ecuador.
 - 1.26. # Residents from Paraguay.
 - 1.27. # Residents from Peru.
 - 1.28. # Residents from Dominican Republic.
 - 1.29. # Residents from Uruguay.
 - 1.30. # Residents from Venezuela.

- 1.31. # Residents from China.
- 1.32. # Residents from China.
- 2. A computed **“.rsa” file** with the adjacency matrix **A** of the province, with a neighborhood radius of 400m. The matrix **A** is a 0-1 symmetric matrix that determines whether any two census tracts are connected geographically, i.e., whether the distance between their centroids is less than 400 meters. The matrix comes in **Harwell-Boeing** format for sparse symmetric matrices with real numbers.
- 3. A computed **“.rua” file** with the transition matrix **P** of the province, with a neighborhood radius of 400m. The matrix **P** is row-stochastic and it has been computed from **A**, where the transition probability to each node is proportional to its total population. The matrix comes in **Harwell-Boeing** format for sparse nonsymmetric matrices with real numbers.

Loading Sparse Matrices

Sparse matrices in Harwell-Boring format (“.rsa” and “.rua” files) can be loaded into Mathematica with the *Import* command. For instance:

```
P = Import["dir/08BarcelonaFinalWeights(0.4).rua ", "HarwellBoeing"];
```

Data sources

- 1. For the number of residents, we have manually downloaded population data at the census-tract level from the INE (National Institute of Statistics): <http://www.ine.es/jaxi/menu.do?type=pcaxis&file=pcaxis&path=%2Ft20%2Fe245%2Fp07%2F%2Fa2009>
We incorporated this data into the “.txt” file.
- 2. We bought the centroids data at the census-tract level from **“Geograma S.L.”** and we also merged them into the “.txt” file.

II- Computation files

- 1. **Computation Example.nb**: A Mathematica file (with explanatory comments) with two simple algorithms for computing the segregation index. It explains two algorithms: the Pagerank-based algorithm (Proposition 3) and the local-segregation-based (Proposition 1). This example consists of a 3x3 matrix.
- 2. **Example Province of Soria.nb**: This file contains the necessary code to reproduce our computations for each province or for Spain as a

whol. It allows to load/create the transition matrix and to compute the segregation indices in the province of Soria.
